The spleen has a diverse set of functions, including hematopoiesis, RBC filtration and storage, and immune surveillance. Despite its many functions, removal of the spleen is commonly performed in dogs and cats with rarely observed long-term adverse sequelae. Splenectomy is indicated in cases of splenic neoplasia, trauma, torsion, and infiltrative disease and, occasionally, as treatment for immune-mediated disorders. It is also commonly performed on an emergency basis for hemoabdomen of splenic origin.

Spleen Anatomy
Clinicians should have an understanding of the splenic and regional vascular anatomy before performing splenectomy. The spleen is located on the left side of the body. The head of the spleen is the craniodorsal-most portion and is attached to the greater curvature of the stomach via the gastrosplenic ligament, in which the short gastric arteries and veins are located. The tail of the spleen is the larger, caudal, more mobile portion that sweeps across the ventral midline, with a loose terminal attachment to the greater omentum.

The main blood supply to the spleen comes from the splenic branch of the celiac artery. This splenic artery runs along the left limb of the pancreas, giving off pancreatic branches before spreading into the vessels supplying the splenic parenchyma. It is important to avoid ligating the splenic vessels proximal to these pancreatic branches to avoid damaging pancreatic blood supply.

The head of the spleen is supplied by the short gastric arteries, which arise from the dorsal branch of the splenic artery and anastomose with the branches of the left gastric artery. The majority of the spleen is supplied by the ventral branch of the splenic artery and its numerous intermediate branches into the hilus. The ventral splenic artery continues as the left gastroepiploic artery.
supplying the greater curvature and fundic portion of the stomach. Ideally, this continuation should be preserved; however, it was shown that sacrifice of the left gastroepiploic vessel did not compromise gastric blood flow or the integrity of the gastric wall in healthy dogs. At the terminal portion of the tail of the spleen, the vessels continue as branches to the omentum.

**Surgical Approach**
The least complicated anatomic approach to splenectomy that ensures no inadvertent ligation of the pancreatic or left gastroepiploic vessels is the hilar ligation technique. With this technique, the vessels are ligated as they terminate into the spleen. The speed of this technique varies depending on the manner of ligation used, with the use of a vessel-sealing device being the fastest, followed by a staple or clip device, and lastly suture ligation. Some devices can seal vessels up to 7 mm in diameter, whereas hemostatic clips are appropriate for vessels up to 3 mm in diameter. With the appropriate size and material, hand ligation with suture can be used in any size vessel for splenectomy. The following describes the hilar approach to splenectomy.

Of note, one study evaluating the relationship between gastric dilatation volvulus and previous splenectomy found dogs with a previous splenectomy to be 5.3 times more likely to develop gastric dilatation volvulus than were dogs without splenectomy. Other studies have reported development of gastric dilatation volvulus in atypical breeds (eg, bichon frise, beagle) after splenectomy, which suggests splenectomy may be a potential predisposing factor. Thus, some surgeons may recommend prophylactic gastropexy be performed in dogs undergoing splenectomy.

With the appropriate size and material, hand ligation with suture can be used in any size vessel for splenectomy.
STEP-BY-STEP SPLENECTOMY: HILAR LIGATION TECHNIQUE

STEP 1
Position the patient in dorsal recumbency (A), and prepare the abdomen with a standard aseptic technique. Drape the patient from xiphoid to pubis (B). In male dogs, maintain the penis out of the sterile field.

WHAT YOU WILL NEED

- Standard general surgery pack including needle holders, thumb forceps, Metzenbaum scissors, suture scissors, and hemostatic forceps (8-12 inches)
- Balfour retractor
- Abdominal laparotomy sponges
- Suction device and Poole suction tip
- Electrosurgery handpiece (helpful, but not required)
- Suture for ligation (generally 2-0 to 3-0 size, depending on patient and pedicle size)
- +/- Hemostatic clip or staple applicator (optional alternative or supplement to sutures)
- +/- Vessel sealing device (optional alternative or supplement to sutures)

Some surgeons may recommend prophylactic gastropexy be performed in dogs undergoing splenectomy.

GASTROPEXY
Find a step-by-step guide to open and laparoscopic-assisted incisional gastropexy at cliniciansbrief.com/article/open-laparoscopic-assisted-incisional-gastropexy
STEP 2

Make a ventral midline abdominal incision from the xiphoid to 2 to 3 cm caudal to the umbilicus (A). The incision can be extended caudally if the size of the mass requires. Using electrosurgical instruments or ligation, remove the falciform fat en bloc to improve exposure (B). In rare cases, extension from midline into a paracostal incision may be indicated for removal of larger splenic masses.

STEP 3

Perform a methodical exploration of the abdomen. If hemoabdomen is present, use suction to remove the hemorrhage and improve visualization. Carefully inspect the liver and the remaining abdominal viscera to monitor for presence of gross metastasis. A liver biopsy is indicated in cases of suspected malignancy regardless of gross appearance (see Liver Biopsy). Gently manipulate the spleen out of the body and onto moistened laparotomy sponges. A diseased spleen is often friable and should be carefully handled to prevent rupture. If the omentum is adhered to a splenic mass, divide the adhesions using electrosurgical devices or ligation. Digital dissection is not recommended, as rupture of the splenic mass may occur.

LIVER BIOPSY

**STEP 4**

The hilar vessels can be visualized as they enter the splenic parenchyma (A). Using hemostatic forceps, bluntly isolate the vessels (B). Using 3-0 absorbable suture, circumferentially double ligate the hilar pedicles (C and D). Before transecting the vessel, place hemostatic forceps on the pedicle close to the spleen (E); this will help prevent splenic bleeding. Repeat this step for all vessels along the splenic hilus until the spleen is removed (F).
After removing the spleen, biopsy any other grossly abnormal tissue. Check the splenic pedicles and biopsy sites for appropriate hemostasis, then gently lavage with warm sterile saline and evacuate the fluid. Perform routine abdominal closure.

Submit the spleen and tissue for histopathologic evaluation.

Postoperative Care & Monitoring

IV fluids should be continued postoperatively and matched to meet the patient’s needs. Ongoing monitoring should include serial packed cell volume checks, continuous ECG for assessment of changes in heart rate and rhythm, twice-daily urine output assessment, body weight monitoring, and serial venous blood gas and lactate monitoring. IV opioid analgesics should not be required for longer than 24 hours unless splenectomy was performed for splenic abscess, in which case antibiotics should be chosen based on results of culture and susceptibility testing and administered for 10 to 14 days.

NexGard is a registered trademark, and TMFRONTLINE VET LABS Marketed by: Frontline Vet Labs™, a Division of Merial, Inc.

NexGard is available in four sizes of beef-flavored soft chewables: 11.3, 28.3, 68 or 136 mg afoxolaner. Each chewable size

Dosage Schedule:

<table>
<thead>
<tr>
<th>Weight Range</th>
<th>Body Weight</th>
<th>Dose of NexGard</th>
</tr>
</thead>
<tbody>
<tr>
<td>4.0 to 10.0 lbs</td>
<td>0.1 to 2.0 lbs</td>
<td>11.3 mg afoxolaner</td>
</tr>
<tr>
<td>10.1 to 24.0 lbs</td>
<td>2.1 to 4.0 lbs</td>
<td>28.3 mg afoxolaner</td>
</tr>
<tr>
<td>24.1 to 35.0 lbs</td>
<td>4.1 to 6.0 lbs</td>
<td>68 mg afoxolaner</td>
</tr>
<tr>
<td>35.1 to 90.0 lbs</td>
<td>6.1 to 12.0 lbs</td>
<td>136 mg afoxolaner</td>
</tr>
</tbody>
</table>

NexGard can be administered with or without food. Care should be taken that the dog consumes the complete dose, and treated animals should be observed for a few minutes to ensure that part of the dose is not lost or refused. It is suspected that any of the dose has been lost if vomiting occurs within two hours of administration, inosculating with another full dose. If a dog is still vomiting, administer additional afoxolaner on a daily basis.

Precautions:

- NexGard may be used in dogs as young as 4 weeks of age. NexGard is not recommended for use in puppies younger than 8 weeks of age because efficacy has not been demonstrated. N1 % (n=415) N 2 % (n=200)
- Reflux of food is possible after NexGard is administered. Use caution with dogs having a history of vomiting or esophageal malformations.
- NexGard is a beef-flavored soft chewable. Do not administer to cats.
- NexGard is contraindicated in dogs with a history of seizures, or dogs that are receiving any anticonvulsant medication.
- NexGard is not recommended for use in dogs with known sensitivity to afoxolaner. Administration of NexGard to dogs with a history of a previous adverse reaction to afoxolaner should be evaluated on a case-by-case basis. Do not administer NexGard to dogs with a history of hepatic encephalopathy.

Adverse Reactions:

- The most common adverse effect associated with NexGard is vomiting. The occurrence of vomiting was generally self-limiting and of short duration. In one study, vomiting occurred within 24 hours of NexGard administration.
- Diarrhea was another common adverse effect associated with NexGard. Diarrhea occurred in 2% of dogs in the afoxolaner treatment group and 1% of dogs in the placebo treatment group.
- Anorexia, lethargy, and fever were also reported as adverse effects in dogs treated with NexGard. These effects were generally mild and self-limiting.

Contraindications:

- NexGard is contraindicated in dogs with a history of seizures.
- NexGard is not recommended for use in dogs with a history of vomiting or esophageal malformations.
- NexGard is not recommended for use in dogs with known sensitivity to afoxolaner.
- Administration of NexGard to dogs with a history of a previous adverse reaction to afoxolaner should be evaluated on a case-by-case basis. Do not administer NexGard to dogs with a history of hepatic encephalopathy.
